Assignment 3 (project)

- Due April 1

Homework 7

- Out today

Reading

- Chapter 10 (ray tracing)

Wolfgang Heidrich

Course Topics for the Rest of the Term

Color

- Today, Friday

Shadows, Ray-tracing & Global Illumination

- Next week

Parametric Curves/Surfaces

Blackbody Radiation

Black body

- Dark material, so that reflection can be neglected
- Spectrum of emitted light changes with temperature
 - This is the origin of the term “color temperature”
 - E.g. when setting a white point for your monitor
 - Cold: mostly infrared
 - Hot: redish
 - Very hot: bluish
- Demo:

Physiology of Vision

The retina

- Rods
 - B/w, edges
- Cones
 - **Color!**
 - 3 types: S, M, L
 - Short (“blue”)
 - Medium (“green”)
 - Long (“red”)

Wolfgang Heidrich

Physiology of Vision

Center of retina is densely packed region called the fovea.

- Cones much denser here than the **periphery**

1.35 mm from retina center

4 μ m

8 mm from retina center

Color/Lightness Constancy

Wolfgang Heidrich

Color Constancy

From Color Appearance Models, fig 8-1

- Automatic “white balance” from change in illumination
- Vast amount of processing behind the scenes!
- Colorimetry vs. perception

Wolfgang Heidrich

Tristimulus Theory of Color Vision

- Although light sources can have extremely complex spectra, it was empirically determined that colors could be described by only 3 **primaries**
- Colors that look the same but have different spectra are called **metamers**
- Metamer demo:
http://www.cs.brown.edu/exploratories/freeSoftware/catalogs/color_theory.html

Wolfgang Heidrich

Color Matching Experiments

Performed in the 1930s

Idea: perceptually based measurement

- Shine given wavelength (λ) on a screen
- User must control three pure lights producing three other wavelengths (say R=700 nm, G=546 nm, and B=438 nm)
- Adjust intensity of RGB until colors are identical

Wolfgang Heidrich

Color Matching Experiment

Results

- It was found that any color $S(\lambda)$ could be matched with three suitable primaries $A(\lambda)$, $B(\lambda)$, and $C(\lambda)$
 - Used monochromatic light at 438, 546, and 700 nanometers
- Also found the space is linear, i.e. if

$$R(\lambda) \equiv S(\lambda)$$

then

$$R(\lambda) + M(\lambda) \equiv S(\lambda) + M(\lambda)$$

and

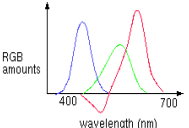

$$k \cdot R(\lambda) \equiv k \cdot S(\lambda)$$

Wolfgang Heidrich

Negative Lobes

Actually:

- Exact target match possible sometimes requires "negative light"
- Some red has to be added to target color to permit exact match using "knobs" on RGB intensity output
- Equivalent mathematically to removing red from RGB output

Wavelength (nm) from 400 to 700. RGB amounts on y-axis. Three curves (R, G, B) are shown. The R curve has a negative lobe between 400 and 500 nm.

Wolfgang Heidrich

Notation

Don't confuse:

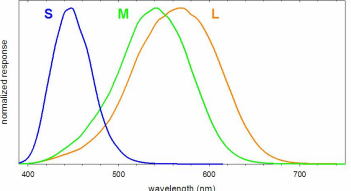

- Primaries: the spectra of the three different light sources: **R, G, B**
 - For the matching experiments, these were **monochromatic** (i.e. single wavelength) light!
 - Primaries for displays usually have a wider spectrum
- Coefficients *R, G, B*
 - Specify how much of **R, G, B** is in a given color
- Color matching functions: *r(λ), g(λ), b(λ)*
 - Specify how much of **R, G, B** is needed to produce a color that is a metamer for pure monochromatic light of wavelength *λ*.

Wolfgang Heidrich

Cone Response Functions

Cone Response

- For every type of cone (short, medium, long), one can also measure how much it responds to illumination at a given wavelength

Wavelength (nm) from 400 to 700. Normalized response on y-axis. Three curves labeled S (short), M (medium), and L (long) are shown.

Wolfgang Heidrich

Color Matching and Cone Response

Linear Algebra View:

- Space of spectra is infinite-dimensional vector space
 - Dot product between two spectra, *S1, S2*:

$$(S_1 \cdot S_2) = \int_{\lambda} S_1(\lambda) S_2(\lambda) d\lambda$$
- Cone responses form a 3D subspace
- Matching functions form the same 3D subspace
- Cone resp. and matching fns are **dual bases**
- Consequence: if the cone resp. overlap and are positive everywhere, they are **not** an orthonormal basis
 - The dual basis (matching functions) then **must** be negative for some wavelengths

Wolfgang Heidrich

Negative Lobes

So:

- Can't generate **all** other wavelengths with **any** set of three **positive** monochromatic lights!

Solution:

- Convert to new synthetic "primaries" to make the color matching easy

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} 2.36460 & -0.51515 & 0.00520 \\ -0.89653 & 1.42640 & -0.01441 \\ -0.46807 & 0.08875 & 1.00921 \end{pmatrix} \begin{pmatrix} R \\ G \\ B \end{pmatrix}$$

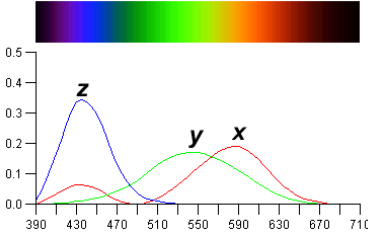

Note:

- R, G, B** are the same monochromatic primaries as before
- The corresponding matching functions *x(λ), y(λ), z(λ)* are now positive everywhere
- But the primaries contain "negative" light contributions, and are therefore not physically realizable

Wolfgang Heidrich

Matching Functions - CIE Color Space

- CIE defined three "imaginary" lights X, Y, and Z, any wavelength *λ* can be matched perceptually by positive combinations

Wavelength (nm) from 390 to 710. Matching functions x, y, z on y-axis. A color bar is shown above the graph.

Wolfgang Heidrich

Matching Functions - Measured vs. CIE Color Spaces

Measured basis

- Monochromatic lights
- Physical observations
- Negative lobes

Transformed basis

- "imaginary" lights
- All positive, unit area matching functions
- Y is luminance, no hue
- X,Z no luminance

Wolfgang Heidrich

Notation

Don't confuse:

- Synthetic primaries X, Y, Z
 - Contain negative frequencies
 - Do not correspond to visible colors
- Color matching functions $x(\lambda)$, $y(\lambda)$, $z(\lambda)$
 - Are non-negative everywhere
- Coefficients X, Y, Z
- Normalized **chromaticity values**

$$x = \frac{X}{X+Y+Z}, y = \frac{Y}{X+Y+Z}, z = \frac{Z}{X+Y+Z}$$

Wolfgang Heidrich

CIE Gamut and λ Chromaticity Diagram

3D gamut

Chromaticity diagram

- Hue only, no intensity

Wolfgang Heidrich

Facts about the CIE "Horseshoe" Diagram

- All visible colors lie inside the horseshoe
 - Result from color matching experiments
- Spectral (monochromatic) colors lie around the border
 - The straight line between blue and red contains the purple tones
- Colors combine linearly (I.e. along lines), since the xy-plane is a plane from a linear space

Wolfgang Heidrich

Facts about the CIE "Horseshoe" Diagram (cont.)

A point C can be chosen as a white point corresponding to an illuminant

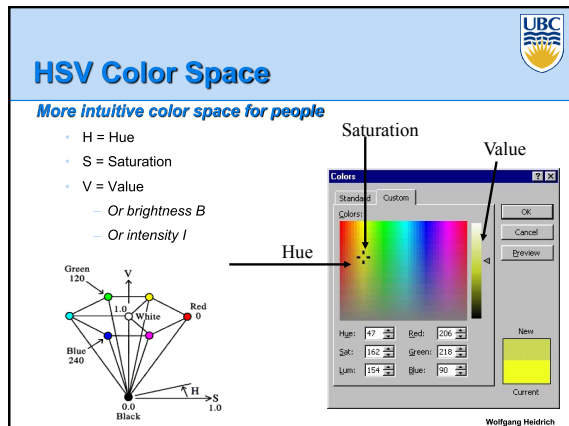

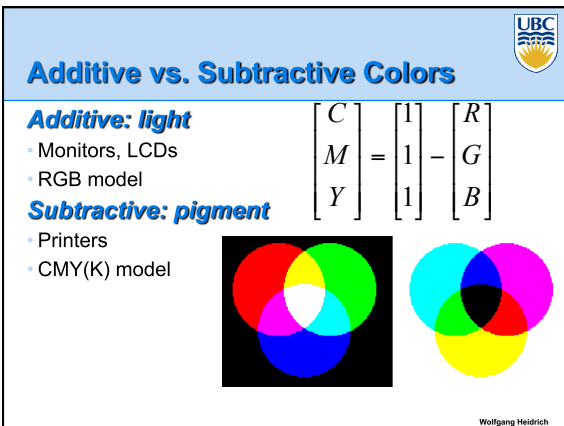

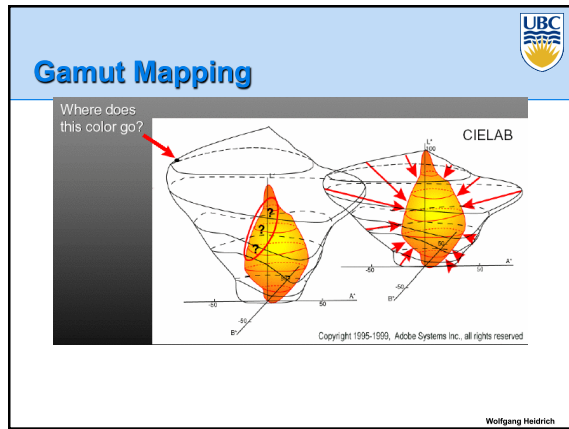

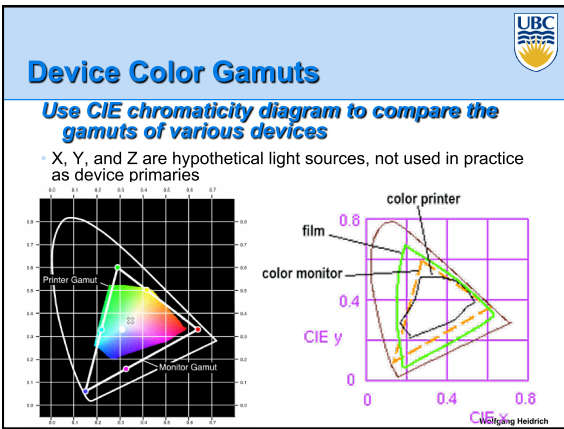

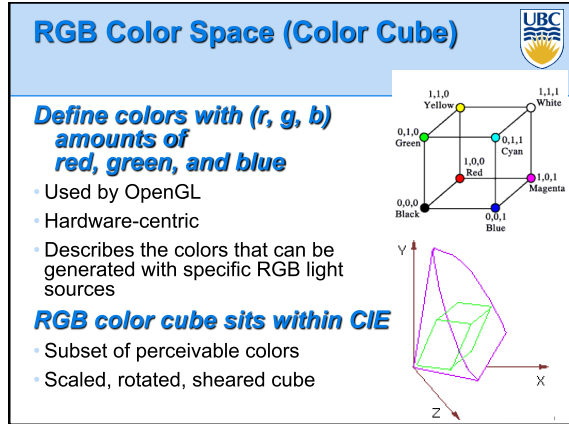

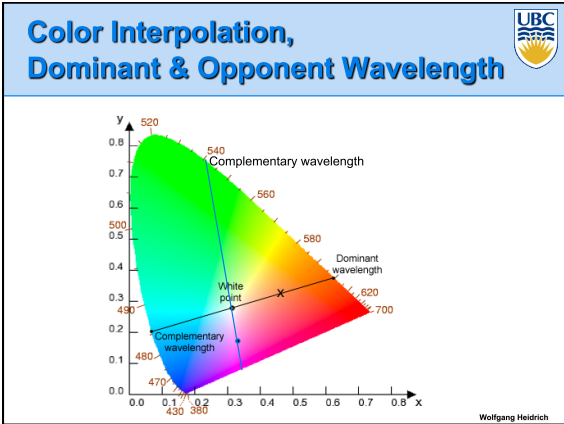

- Usually this point is of the curve swept out by the black body radiation spectra for different temperatures
- Relative to C, two colors are called complementary if they are located along a line segment through C, but on opposite sides (I.e C is an affine combination of the two colors)
- The dominant wavelength of the color is found by extending the line from C through the color to the edge of the diagram
- Some colors (I.e. purples) do not have a dominant wavelength, but their complementary color does

Wolfgang Heidrich

CIE Diagram

- Blackbody curve
- Illumination:
 - Candle 2000K
 - Light bulb 3000K (A)
 - Sunset/sunrise 3200K
 - Day light 6500K (D)
 - Overcast day 7000K
 - Lightning >20,000K

Wolfgang Heidrich

Monitors

Monitors have nonlinear response to input

- Characterize by **gamma**
 - $displayedIntensity = a^\gamma (maxIntensity)$

Gamma correction

- $displayedIntensity = \left(a^{1/\gamma} (maxIntensity) \right)^\gamma$
= $a (maxIntensity)$

Gamma for CRTs:

- Around 2.4

Wolfgang Heidrich

Coming Up...

Wednesday

- Shadows

Friday:

- Ray-tracing
