

Using Implicit Edge Equations

Usage:

- Go over each pixel on screen
 - To be efficient restrict to bounding rectangle
- Check if pixel is inside/outside of triangle
 - Use sign of edge equations

Computing Edge Equations

Implicit equation of a triangle edge:

$$L(x, y) = \frac{(y_e - y_s)}{(x_e - x_s)}(x - x_s) - (y - y_s) = 0$$

- see Bresenham algorithm
- L(x,y) positive on one side of edge, negative on the other
- Question:
 - What happens for vertical lines?

Scan Conversion- Polygons

Edge Equations

Multiply with denominator

$$L(x,y) = (y_e - y_s)(x - x_s) - (y - y_s)(x_e - x_s) = 0$$

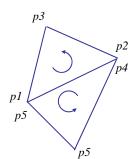

- Avoids singularity
- Works with vertical lines
- What about the sign?
 - Which side is in, which is out?

Edge Equations

- Determining the sign
 - Which side is "in" and which is "out" depends on order of start/end vertices...
 - Convention: specify vertices in counterclockwise order

Scan Conversion- Polygons

Edge Equations

- Counter-Clockwise Triangles
 - The equation L(x,y) as specified above is negative inside, positive outside
 - Flip sign:

$$L(x,y) = -(y_e - y_s)(x - x_s) + (y - y_s)(x_e - x_s) = 0$$

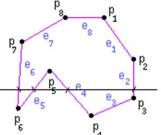

- Clockwise triangles
 - Use original formula

$$L(x,y) = (y_e - y_s)(x - x_s) - (y - y_s)(x_e - x_s) = 0$$

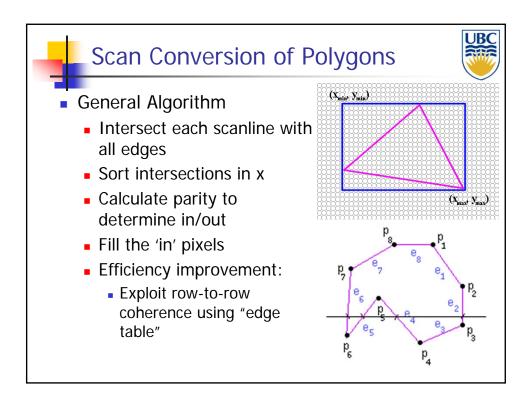

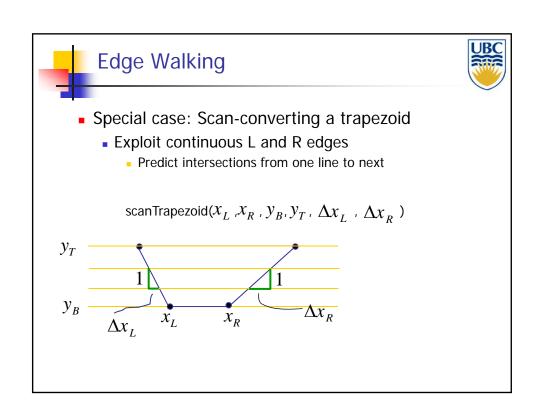

- Implicit formulation doesn't work for non-convex polygons
- Require per pixel, per edge computation
- Observation:
 - Straight line intersection with polygon = set of segments

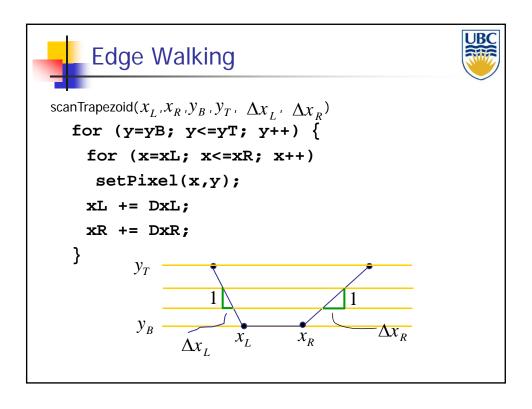

- Alternative: algorithm based on scan-line/edge intersections
 - Works for general polygons
 - Less per pixel computations

Scan Conversion- Polygons

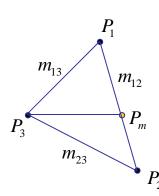

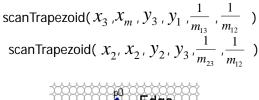

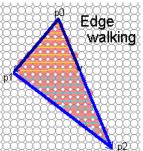

Edge Walking Triangles

 Split triangles into two "trapezoids" with continuous left and right edges

Scan Conversion- Polygons

Edge Walking Triangles

Issues

- Many applications have small triangles
 - Setup cost is non-trivial
- Clipping triangles produces non-triangles
 - Can be avoided through re-triangulation

Discussion

- Old hardware:
 - Use edge-walking algorithm
 - Scan-convert edges, then fill in scanlines
 - Compute interpolated values by interpolating along edges, then scanlines
 - Requires clipping of polygons against viewing volume
 - Faster if you have a few, large polygons
 - Possibly faster in software

Scan Conversion- Polygons

Discussion:

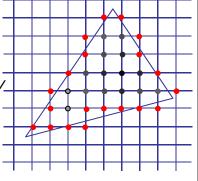

- Modern GPUs:
 - Use edge equations
 - Plus plane equations for attribute interpolation
 - No clipping of primitives required
 - Faster with many small triangles
- Additional advantage:
 - Can control the order in which pixels are processed
 - Allows for more memory-coherent traversal orders
 - E.g. tiles or space-filling curve rather than scanlines

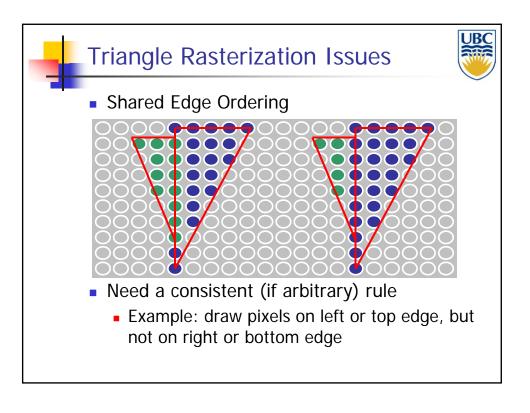

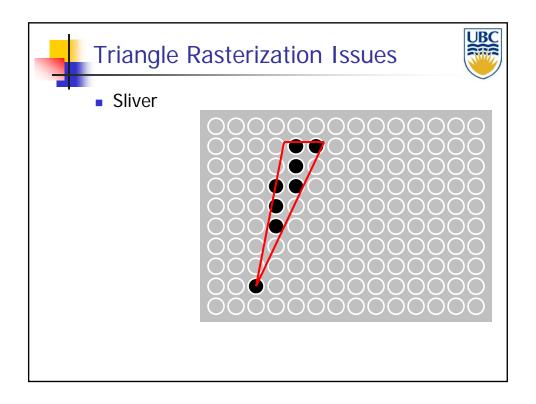

Rasterization Issues (Independent of Algorithm)

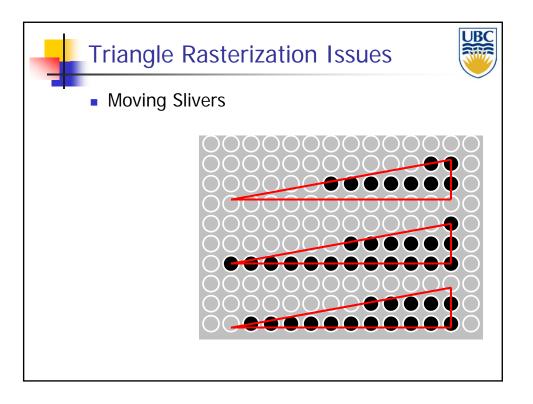

- Exactly which pixels should be lit?
 - Those pixels inside the triangle edge (of course)
 - But what about pixels exactly_ on the edge?
 - Don't draw them: gaps possible between triangles
 - Draw them: order of triangles matters

Scan Conversion- Polygons

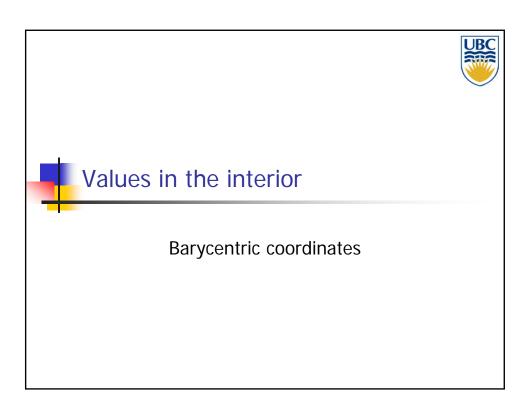

Triangle Rasterization Issues

- These are ALIASING Problems
 - Problems associated with representing continuous functions (triangles) with finite resolution (pixels)
 - More on this problem when we talk about sampling...

Scan Conversion- Polygons

Interpolation – access triangle interior

- Interpolate between vertices:
 - Z
 - r,g,b colour components
 - u,v texture coordinates
 - N_x, N_y, N_z surface normals
- Equivalent
 - Barycentric coordinates
 - Bilinear interpolation
 - Plane Interpolation

Scan Conversion- Polygons

Barycentric Coordinates

Area

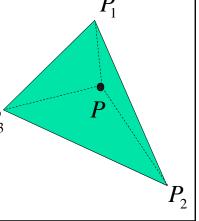

$$A = \frac{1}{2} \left\| \overrightarrow{P_1 P_2} \times \overrightarrow{P_1 P_3} \right\|$$

Barycentric coordinates

$$a_1 = A_{P_2P_3P} / A, a_2 = A_{P_3P_1P} / A,$$

 $a_3 = A_{P_1P_2P} / A,$

$$P = a_1 P_1 + a_2 P_2 + a_3 P_3$$

Barycentric Coordinates

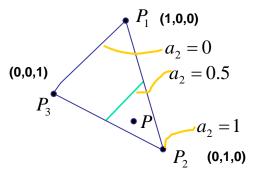

weighted combination of vertices

$$P = a_1 \cdot P_1 + a_2 \cdot P_2 + a_3 \cdot P_3$$

$$a_1 + a_2 + a_3 = 1$$

$$0 \le a_1, a_2, a_3 \le 1$$

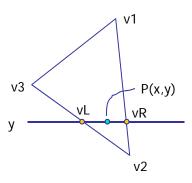

Scan Conversion- Polygons

Alternative formula: **Bi-Linear Interpolation**

- Interpolate quantity along L and R edges
 - (as a function of y)
 - Then interpolate quantity as a function of x

Bi-Linear interpolation

■ Formulation
$$P = \frac{c_2}{c_1 + c_2} \cdot P_L + \frac{c_1}{c_1 + c_2} \cdot P_R$$

$$P_L = \frac{d_2}{d_1 + d_2} P_2 + \frac{d_1}{d_1 + d_2} P_3$$

$$P_R = \frac{b_2}{b_1 + b_2} P_2 + \frac{b_1}{b_1 + b_2} P_1$$

$$P = \frac{c_2}{c_2} \left(\frac{d_2}{d_2} P_2 + \frac{d_1}{d_2} \right)$$

$$P = \frac{c_2}{c_1 + c_2} \left(\frac{d_2}{d_1 + d_2} P_2 + \frac{d_1}{d_1 + d_2} P_3 \right) + \frac{c_1}{c_1 + c_2} \left(\frac{b_2}{b_1 + b_2} P_2 + \frac{b_1}{b_1 + b_2} P_1 \right)$$

Scan Conversion- Polygons

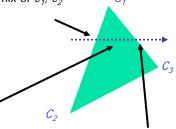

Bi-Linear Interpolation

- Most common approach, and what OpenGL does
 - Perform Phong lighting at the vertices
 - Linearly interpolate the resulting colors over faces
 edge: mix of c₁, c₂
 - Along edges
 - Along scanlines
- Equivalent to Barycentric Coordinates!

interior: mix of c1, c2, c3

edge: mix of c1, c3

Another Alternative: Plane Equation

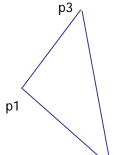

- Observation: Values vary linearly in image plane
 - E.g.: r = Ax + By + C
 - r= red channel of the color
 - Same for g, b, Nx, Ny, Nz, z...
 - From info at vertices we know:

$$r_1 = Ax_1 + By_1 + C$$

$$r_2 = Ax_2 + By_2 + C$$

$$r_3 = Ax_3 + By_3 + C$$

- Solve for A, B, C
- One-time set-up cost per triangle & interpolated value

Scan Conversion- Polygons

Discussion

- Which algorithm (formula) to use when?
 - Bi-linear interpolation
 - Together with trapezoid scan conversion
 - Plane equations
 - Together with implicit (edge equation) scan conversion
 - Barycentric coordinates
 - Too expensive in current context
 - But: method of choice for ray-tracing
 - Whenever you only need to compute the value for a single pixel

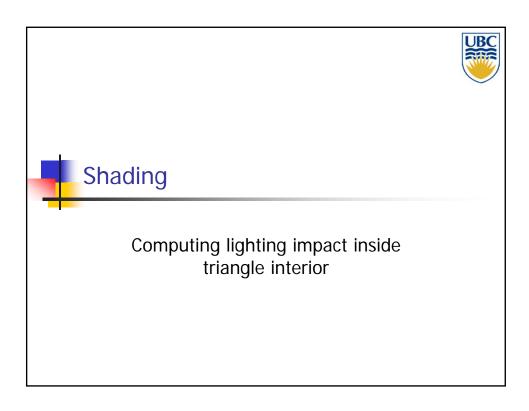

Validation

- All formulations should provide same value
- Can verify barycentric properties

$$a_1 + a_2 + a_3 = 1$$

$$0 \le a_1, a_2, a_3 \le 1$$

- Input to Scan Conversion:
 - Vertices of triangles (lines, quadrilaterals...)
 - Color (per vertex)
 - Specified with glColor
 - Or: computed with lighting
 - World-space normal (per vertex)
 - Left over from lighting stage
- Shading Task:
 - Determine color of every pixel in the triangle

Scan Conversion- Polygons

Shading

- How can we assign pixel colors using this information?
 - Easiest: flat shading
 - Whole triangle gets one color (color of 1st vertex)
 - Better: Gouraud shading
 - Linearly interpolate color across triangle
 - Even better: Phong shading
 - Linearly interpolate the normal vector
 - Compute lighting for every pixel
 - Note: not supported by rendering pipeline as discussed so far

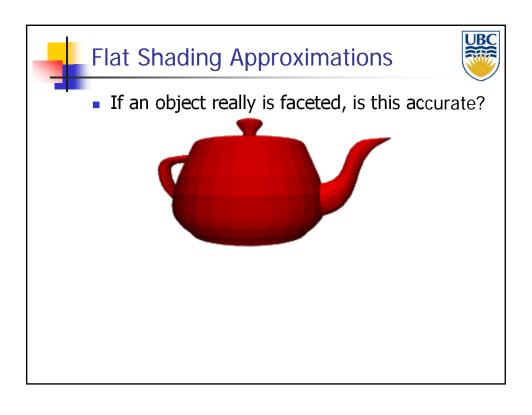

Flat Shading

 Simplest approach: calculate illumination at one point per polygon (e.g. center)

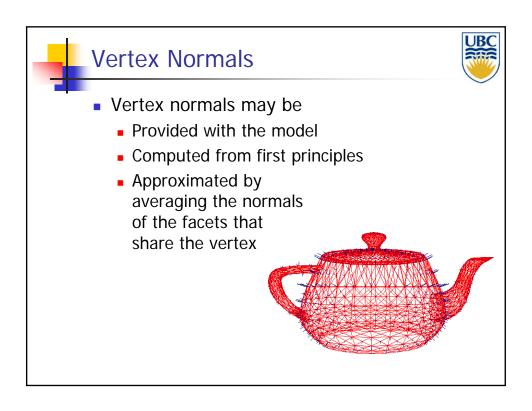

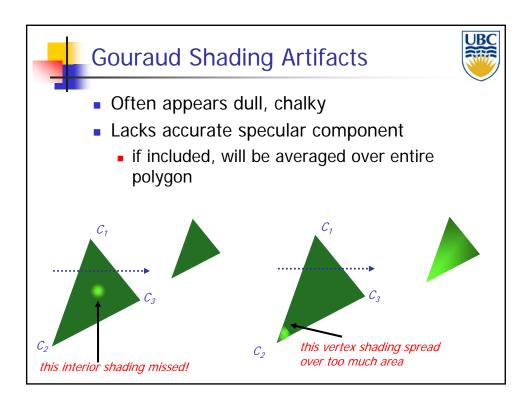

Obviously inaccurate for smooth surfaces

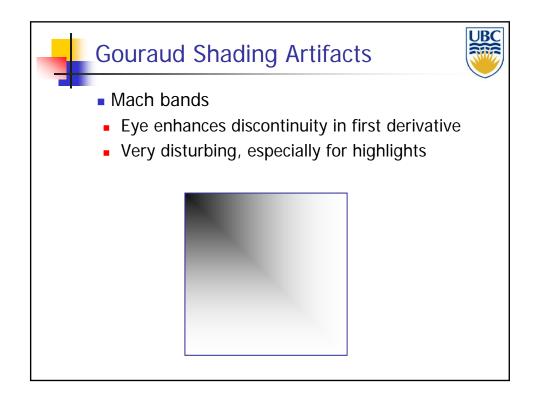

Scan Conversion- Polygons

Phong Shading

- linearly interpolating surface normal across the facet, applying Phong lighting model at every pixel
 - Same input as Gouraud shading
 - Pro: much smoother results
 - Con: considerably more expensive

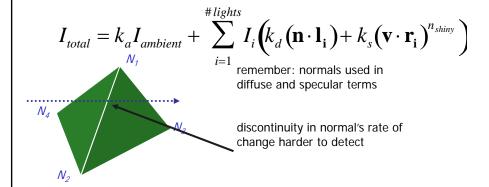

- Not the same as Phong lighting
 - Common confusion
 - Phong lighting: empirical model to calculate illumination at a point on a surface

Phong Shading

- Linearly interpolate the vertex normals
 - Compute lighting equations at each pixel
 - Can use specular component

Scan Conversion- Polygons

Phong Shading Difficulties

- Computationally expensive
 - Per-pixel vector normalization and lighting computation!
 - Floating point operations required
- Lighting after perspective projection
 - Messes up the angles between vectors
 - Have to keep eye-space vectors around
- No direct support in standard rendering pipeline
 - But can be simulated with texture mapping, procedural shading hardware (see later)
