1 Comparing Orders of Growth for Functions

For each of the functions below, give the best Θ bound you can find and then arrange these functions by increasing order of growth.

$$\begin{array}{ll}
n + n^2 & 2^n \\
55n + 4 & 1.5n \lg n \\
n! & \ln n \\
2n \log(n^2) & \frac{n}{\log n} \\
(n \lg n)(n+1) & (n+1)!
\end{array}$$

 1.6^{2n}

tricky, but doable!

2 Functions/Orders of Growth for Code

Give and briefly justify good Θ bounds on the worst-case running time of each of these pseudocode snippets dealing with an array A of length n. Note: we use 1-based indexing; so, the legal indexing of A is: $A[1], A[2], \ldots, A[n]$.

Finding the maximum in a list:

```
Let max = -infinity
For each element a in A:
  If max < a:
    Set max to a
Return max
   "Median-of-three" computation:
Let first = A[1]
Let last = A[n]
Let middle = A[floor(n/2)]
If first <= middle And middle <= last:</pre>
  return middle
Else If middle <= first And first <= last:</pre>
  return first
Else:
  return last
   Counting inversions:
Let inversions = 0
For each index i from 1 to n:
  For each index j from (i+1) to n:
    If a[i] > a[j]:
      Increment inversions
Return inversions
   Repeated division:
Let count = 0
While n > 0:
    count = count + 1
    n = floor(n/2)
```

Return count

3 Progress Measures for While Loops

Assume that FindNeighboringInversion(A) consumes an array A and returns an index i such that A[i] > A[i+1] or returns -1 if no such inversion exists. Let's work out a bound on the number of iterations of the loop below in terms of n, the length of the array A.

```
Let i = FindNeighboringInversion(A)
While i >= 0:
   Swap A[i] and A[i+1]
   Set i to FindNeighboringInversion(A)
```

1. Give and work through two small inputs that will be useful for studying the algorithm. (What is "useful"? Try to find one that is simply common/representative and one that really stresses the algorithm.)

2. Define an inversion (not just a neighboring one), and sketch the key points in a proof that if any inversion exists, a neighboring inversion exists.

3. Give upper- and lower-bounds on the number of inversions in A.

4. Give a "measure of progress" for each iteration of the loop in terms of inversions. (I.e., how can we measure that we're making progress toward terminating the loop?)

5. Give an upper-bound on the number of iterations the loop could take.

6. Prove that this algorithm sorts the array A.

4 Challenge Problem

- 1. Give the best Θ bound you can find for $\sqrt{n}^{\sqrt{n}}$ and then arrange it with respect to the other functions from the "1" section.
- 2. Imagine that rather than FindNeighboringInversion, we'd used FindInversion, which returns two arbitrary indices (i, j) such that i < j but A[i] > A[j] and then in our loop swapped A[i] and A[j]. Could the loop run forever? If it terminates, would the array be sorted? Can you upper- and lower-bound the loop's runtime? Comparing the "neighboring" version to this version, how important is it which inversion is found?
