Midterm Practice Questions

Note: These questions are to provide additional practice for the midterm exam. The format and coverage of the midterm may not be the same.

Midterm Appendix
You can use the midterm appendix posted to the course website when answering these questions. It will be provided to you on the exam.

1. Short Answer

1.1. Python allows you to enter strings using either single quotes ('), double quotes (") or triple quotes ("""). Is it necessary to provide all these options? If it is necessary, briefly explain why. If it is not necessary, briefly explain why Python allows the options anyway.

1.2. Suppose we define a Python module for estimating personal income tax and save it in a file named income.py. What would this module’s name be when we open it in Spyder and run it by clicking the green arrow? What would this module’s name be when we import it in another Python program that is stored in a file called myincome.py?

2. Code Tracing

2.1. What are the contents of counter and changes after the following script is run?
2.2. Consider the following function:

```python
def bar1(y):
    x = 0
    z = ""
    while x < len(y):
        if x % 2 == 0 :
            z = z + y[x]
        x = x + 1
```

Where `len(s)`, `s[k]`, and `x % y` are the string operators explained in the appendix at the end of this document.

Suppose the main program that calls this function has the following statements:

```python
x = 20
y = "big deal"
r = bar1(y)
```

What are the values of `x`, `y`, `z` and `r` after these statements are executed?

2.3. Consider the following python code:

```python
def bar1(y):
    x = 0
    z = ""
    while x < len(y):
        if x % 2 == 0 :
            z = z + y[x]
        x = x + 1
    return z

# Main Program
x = 20.0
y = "big deal"
r = bar1(y)
```

What are the values of `x`, `y`, and `r` after these statements are executed?

2.4. Consider the following code:

```python
n = 0
text = "Python is a different language than Scratch"
text = ""
vtext = "aeiouy"
for p in text:
    if p in vtext:
        n += 1
    else:
        ntext += p
```
What are the values of \( n, \text{text}, \text{ntext} \) and \( \text{vtext} \) after executing this code?

### 3. Code Summarization

3.1. **Briefly summarize** what the following Python function does when it is called with a string as its first argument a character (a string with one character) as its second argument and a number as its third argument.

```python
def foo(str1, char, n):
    res = ''
    for i in range(len(str1)):
        if(len(res) < n):
            res = res + str1[i] + char
    return res
```

What will the function return if it is called by the statement `foo("Hello World", "+", 6)`?

3.2. **Briefly summarize** what the following Python function does when called with a string as its argument.

```python
def grap(x):
    z = ""
    for y in x:
        z = y + z
    return z
```

3.3. **Briefly summarize** the effect of the function `bar1` in question 2.3 above.
4. Fill in the Code

4.1. Fill in the missing lines of code in the following code. The code reads in a limit amount and a list of prices and prints the largest price that is less than the limit. You can assume that all prices and the limit are positive numbers. When a price 0 is entered the program terminates and prints the largest price that is less than the limit if there was one, or a message indicating that no price was less than the limit.

```python
# Read the limit
limit = float(input("Enter the limit: "))
max_price = 0
# Read the next price
next_price = float(input("Enter a price or 0 to stop: "))

while next_price > 0 :
    << write your code here >>

    # Read the next price
    << write your code here >>

if max_price > 0:
    << write your code here >>
else :
    << write your code here >>
```

4.2. Write a Python version of the Scratch code in question 2.1 above. If the Scratch code changes the sprite's values (like its position or costume, etc), your program should just print out the changes.
5. Find the Bug

5.1. There is a bug in the following function; in other words, the function does not do what the docstring says that it does. Where is the bug? How might you fix it?
You should assume that the function `retain(original_string, filter_string)` is defined, has no bugs and returns the characters of the original string that appear in the filter string. For instance, `retain("introduction", "ion")` will return "inoion".

Note that a DNA sequence is a string in which each character is G, C, A or T. For instance "AGGAAGGGAATTAGCAGC" is a DNA sequence, while "CGGACUNGCATATAT" is not.

```python
def compute_ratio(seq):
    """ (str) -> int
    Compute the GC ratio for a sequence.

    Inputs: seq - A string containing a sequence of characters.

    Outputs: A integer number specifying the percentage of GC in the sequence. That is, a value 15 means that 15% of the sequence bases are either G or C. If the sequence is not DNA (eg: if there are any sequence characters which are not G, C, A, or T), then None is returned.
    
    >>> compute_ratio("AAATGGGCC")
    55
    """
    gc = retain(seq, "GC")
    at = retain(seq, "AT")
    if len(gc) + len(at) != len(seq):
        return None
    return len(gc) // len(seq)
```

6. Write Code

6.1. Define a function `print_triangle` which implements the following task. Do not forget to include a header line.

- Input: A character `char` and a positive integer `n`.
- Task: Prints an isosceles triangle filled with the given character whose orientation is as following: The triangle’s base spans over 2n lines and is at the leftmost end of the page, and its top vertex is between the n-th and (n+1)-th lines.
• For instance `print_triangle("*", 4)` will print the following
  *
  **
  ***
  ****
  ****
  ***
  **
  *

6.2. Write a version of the function `bar1()` from question 2.3 that uses a for loop instead of a while loop.

7. Testing
7.1. Consider again the function that computes the GC ration of a DNA sequence which was defined in 5.1. The function header and specification (docstring) is as following:

```python
def compute_ratio(seq):
    """ (str) -> int
    Compute the GC ratio for a sequence.

    Inputs: seq - A string containing a sequence of characters.

    Outputs: A integer number specifying the percentage of GC in the sequence. That is, a value 15 means that 15% of the sequence characters are either G or C. If the sequence is not DNA (eg: if there are any sequence characters which are not G, C, A, or T), then None is returned.

    >>> compute_ratio("AAATGGGCC")
    55
    """
```

Following the guidelines we discuss in the class, list a set of test cases that will provide a good black box testing for this function.

7.2. Add the doctest with the cases you defined in 7.2 in the docstring for this function.

Note: When The returned value is expected to be `None`, you indicate that with an empty line in the doctest. That is, the value of `None` is nothing. (It is fine for the exam if you write `None` instead of empty line, but doctest won’t accept it.)
8. Importing and using modules

Below is the code contained within a file, `baz.py`:

```python
def spam(x):
    print ('Spam says its home is', __name__)
    return x / 5

def eggs(x):
    print ('Eggs says its home is', __name__)
    return x + 3

if __name__ == '__main__':
    print ('I'm home!')
else:
    print ('This isn't where I live...')
```

8.1. If the following commands are typed into the console in succession, with the directory containing `baz.py` being the current directory, what will appear in the console? If an error is thrown, briefly describe why the error occurred.

```python
>>> import baz

>>> spam(10)

>>> from baz import spam
```

8.2. If you needed to use the function `spam(x)` from `baz`, give one advantage and one disadvantage of using the command `from baz import spam` instead of just `import baz`. Answers which give more than one of each will receive zero points.

8.3. If `baz.py` were to be run in Spyder (by clicking the green arrow), rather than imported, what would be printed on the screen if the following commands were typed into the console? If an error is thrown, briefly describe why the error occurred.

```python
>>> baz.eggs(3)

>>> import baz

>>> eggs(spam(5))
```
9. **Strings and Methods**

9.1. Explain the main differences between a method and a function

9.2. Assume in the questions below the variable $s$ contains a DNA sequence such as:

$$s = 'acgtaTgTtAaGcGcCc'$$

Write a Python command(s) to count the number of Guanine (G or g) bases using **object notation**.

Write the same python command as above, but this time using **regular function notation**.
