

# CPSC 317 COMPUTER NETWORKING

Module 7: Link Layer – Day 4 – Physical and Link Layer Issues

1

# LEARNING GOALS

## **The physical layer and advanced link layer issues**

- Describe how bits are transmitted on a medium
- Explain the timing of sending and receiving bits and packets
- Enumerate and describe the various media that can be used at the physical layer
- Describe the purpose and mechanism of VLANs
- Describe the unique problems of data-center computing
- Describe the possible architectures of data-center networking

# READING

- Reading: 1.2.1, 1.2.2, 6.4.4, 6.6

# THE PHYSICAL LAYER

There are many different media that can support networking

- Co-axial cable
- Twisted pair (phone cables)
- Fiber
- Radio
  - WiFi
  - Bluetooth
  - Cellular
  - Satellite

# MODULATION

- How bits are put on the medium is an electrical engineering issue, but generally there is a “carrier” signal which is modulated to contain the data
- AM
  - Amplitude modulation
- FM
  - Frequency modulation
- PM
  - Phase modulation

# AMPLITUDE MODULATION

## Amplitude Modulation (AM)

Input (Modulating Wave)

Carrier

Modulated Result

# FREQUENCY MODULATION

## Frequency Modulation (FM)

Input (Modulating Wave)

Carrier

# PHASE MODULATION

# SENDING THE BITS

- Almost all physical networks send the bits of the message one at a time on the medium
  - Code-Division multiplexing complicates this because a single code symbol generally encodes more than one bit
- The timing of when bits are sent is determined by the bandwidth of the medium
  - 10 Mbps: one bit every 100ns
  - 100 Mbps: one bit every 10ns
  - 1 Gbps: one bit every 1ns
  - 10 Gbps: one bit every 100ps
- The timing of when bits arrive is determined by the propagation time and the send timing

# A SCENARIO

- A sender is sending 8 bits to a receiver
- Propagation time is 5 time units
- Transmission time is 1 time unit per bit
- A realistic scenario:
  - 100Mbps network
  - Distance between sender and receiver is 10 metres
  - A time unit is 10ns
  - In 50ns the signal will travel  $50 * 10^{-9} * 2 * 10^8 = 10\text{m}$

# TIME TO DELIVER A MESSAGE

- Transmission time
  - 1 time unit per bit
- Propagation time (bit)
  - Only for the last bit
- Total time = Transmission time + Propagation time
  - A sender is sending 8 bits to a receiver
  - Propagation time is 5 time units
  - Transmission time is 1 time unit per bit
  - Total time =  $5 * 1 + 8 = 13$

# A PROBLEM WITH LANS

- Having a single large LAN is sometimes less than ideal
  - All broadcast traffic goes to every adapter
  - Privacy and security
    - Anyone using Wireshark can see any frames
- Creating separate LANs would solve the problem
  - One LAN for each group in a company, for example
  - But each LAN needs a switch
  - Many small switches are more expensive than a single large switch

# WHAT IF WE COULD ...

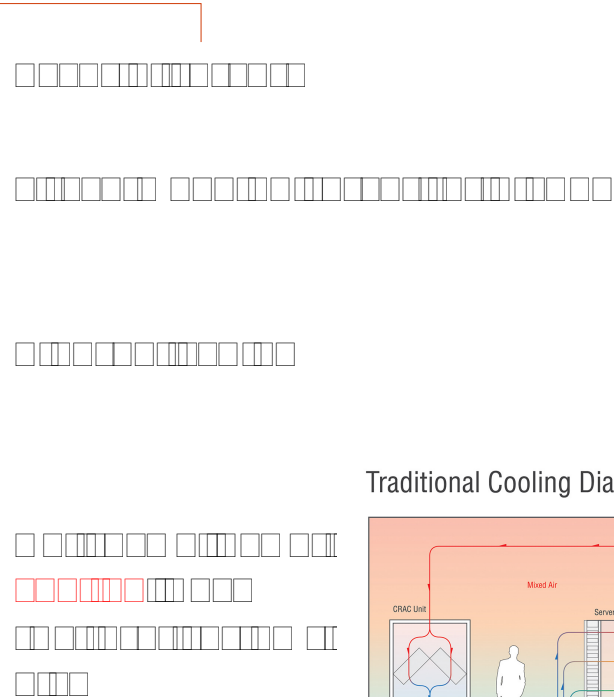

- Have multiple virtual LANs using a single switch
- Enter the Virtual Local Area Network – VLAN
- Since switches contain software forwarding already, it is possible to create multiple VLANs on a single switch
  - Identified by port
  - Identified by MAC address
- With a bit more software, the switch hardware can also be the router that connects these VLANs together

# DATA CENTER NETWORKING

- The networking needs of data centers are unique
- 10,000 – 100,000 of computers in a small space
- Distributed algorithms run on these computers
  - Spark, Hadoop, TensorFlow, etc
  - Communication is a key component
- How are these things connected together?

# DATA CENTER NETWORKING

- The networking needs of data centers are unique
- 10,000 – 100,000 of computers in a small space
- Distributed algorithms run on these computers
  - Spark, Hadoop, TensorFlow, etc
  - Communication is a key component
- **How are these things connected together?**

# A HIERARCHICAL STRUCTURE

Figure 5.30 ♦ A data center network with a hierarchical topology

# DATA CENTER CHARACTERISTICS

- Network speeds up to 100 Gbps
- 20-40 servers per rack
- How efficient is communication in this setting?
  - Within a rack?
  - Between racks?

# CLICKER QUESTION

40 servers per rack  
100Gbps bandwidth

Suppose all 40 servers in a rack need to talk to a different server in the same rack. What is the bandwidth of each connection?

- A. 100Gbps
- B. 2.5Gbps

# CLICKER QUESTION

40 servers per rack  
100Gbps bandwidth

Suppose all 40 servers in one rack need to talk to the corresponding server in a different rack. What is the bandwidth of each connection?

- A. 100Gbps
- B. 2.5Gbps
- C. It depends on where the two racks are physically
