Naomi Kam

## EXAMPLE: Salad Dressing

Bottle	Oil	Vinegar
A	15%	36%
B	9%	21%

- Can we mix bottles to get 13% of oil and 31% of vinegar?

-> **Yes! 2 Parts A and 1 part B**

$$\text{Oil: } \frac{2}{3}(15\%) + \frac{1}{3}(9\%) = 13\%$$

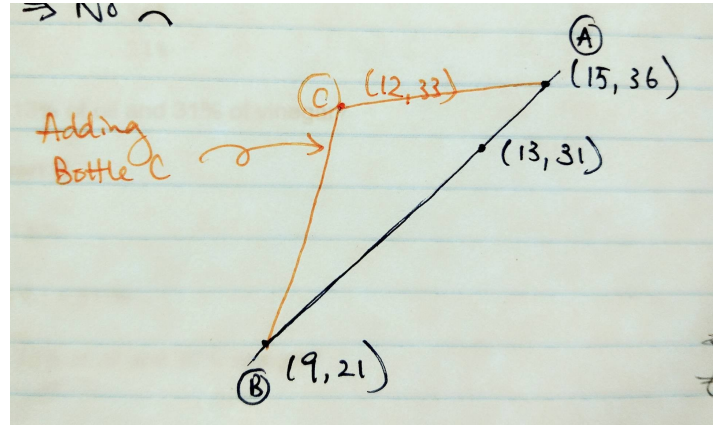

$$\text{Vinegar: } \frac{2}{3}(36\%) + \frac{1}{3}(21\%) = 31\%$$

- Can we mix bottles to get 12% of oil and 30% vinegar?

-> **No :(**

Referring to the figure above, the black line segment reflects the solutions obtainable by mixing bottles A and B.

If another bottle C of 12% oil and 33% vinegar is added (as shown by the orange line segment), then we can not only obtain a mixture of 12% oil and 30% vinegar, but any points enclosed within the triangle formed by A, B, and C.

A **mixture** is a **convex combination** of points representing the contents of the bottles, where points  $p_1, p_2, \dots, p_n$  is  $\sum_{i=1}^n \alpha_i p_i$  such that

- $\sum_{i=1}^n \alpha_i = 1$
- $\alpha_i \geq 0$  for all  $i$

# Convex Hulls (CH(P))

**Convex hull (CH(P))** of a set of points  $P$  is the smallest convex set containing  $P$ , the set of all convex combinations of  $P$ .

A set  $T$  is **convex** if for all  $a, b \in T$ , segment  $ab$  is in  $T$ .

The boundary of the convex combination are bounded by the perimeter points of the set.

## Problem

**Input:** set of points  $P = p_1 p_2 \dots p_n$

**Output:** convex hull of  $P$

## Approach 1: Jarvis March ("Gift-wrapping") 1973

### Gist of Algorithm

#### Jarvis march

- Start at the leftmost point in the set (if there are multiple, take the closest to the bottom)
- For all other points, compute the angle measured ccw with down being  $0^\circ$
- Take point with smallest angle
- Repeat, except for further steps, measure angles ccw with the line segment from current to previously selected point being  $0^\circ$

### Pseudocode from Class

1. Find point  $p_0$  in  $P$  with minimum y-coordinate ----  $O(n)$
  2. set  $h = 0$  ----  $O(1)$
  3. **repeat** for each  $p \in P$ 
    - if  $\text{rightturn}(p_h, q, p)$
    - $q = p$
  - $p_{h+1} = q$
  - $h = h + 1$
- until**  $p_h = p_0$

### Algorithm Jarvis' March [1973]

{ gift-wrapping method, generalizes to higher dimensions }  
 Step 1: Let  $p_1$  be the point with minimum y-coordinate (lex.)  
 Step 2: Anchor ray at current point and rotate to next anchor point.  
 Repeat.

**Output-sensitive:**  $O(nh)$  time.  
 $n = \#$  input points,  $h = \#$  hull vertices (output size)  
 $(3 \leq h \leq n \text{ if } n \geq 3 \text{ and not all points collinear})$

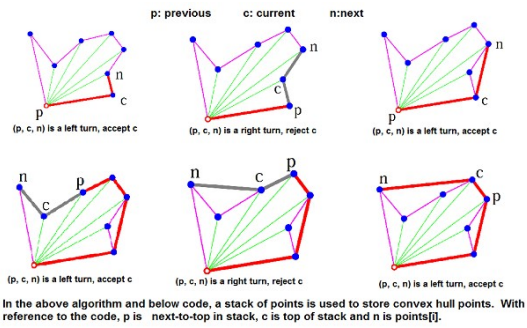

**Worst-case:**  $O(n^2)$  time.

## Approach 2: Graham's Scan (1972)

GRAHAM-SCAN( $Q$ )

- 1 let  $p_0$  be the point in  $Q$  with the minimum  $y$ -coordinate,  
or the leftmost such point in case of a tie
- 2 let  $(p_1, p_2, \dots, p_m)$  be the remaining points in  $Q$ ,  
sorted by polar angle in counterclockwise order around  $p_0$   
(if more than one point has the same angle, remove all but  
the one that is farthest from  $p_0$ )
- 3 let  $S$  be an empty stack
- 4 PUSH( $p_0, S$ )
- 5 PUSH( $p_1, S$ )
- 6 PUSH( $p_2, S$ )
- 7 for  $i = 3$  to  $m$
- 8     while the angle formed by points NEXT-TO-TOP( $S$ ), TOP( $S$ ),  
        and  $p_i$  makes a nonleft turn
- 9         POP( $S$ )
- 10        PUSH( $p_i, S$ )
- 11 return  $S$
