

## Applications of Network Flows

**Last time:** Max matching in bipartite graph is defined by the maximum flow.

**Proof:** Max flow will give a maximum matching.

Consider the main property of a bipartite graph: vertices in one partition have no connections between them. That allows us to set up "disjoint" unique paths from  $s$  to  $t$ . Where "disjoint" means that no two paths go through same vertex in either partition. For example, by having a unit flow on the  $s \rightarrow v \rightarrow u \rightarrow t$  path, we can't have flow on the  $s \rightarrow v \rightarrow w \rightarrow t$  path. On this property we'll base our proof.

**Claim:**

- 1) If  $M$  is a matching in a bipartite graph  $G$ , then there exists a flow  $f$  in  $F$  (flow network for  $G$ ) such that  $size(f) = |M|$ . In other words, we can write:  
 $size(f^*) \geq |M^*|$ , where  $f^*$  is a max flow and  $M^*$  is a size of maximum matching set.
- 2) If  $f$  is an integer value flow in  $F$ , then there exists a matching  $M$  in  $G$  of size  $size(f)$ .  
 $size(f^*) \leq |M^*|$

For the claim # 2, let  $M = \{(u, v) \in G \mid f(u, v) = 1\}$  then  $M$  forms a matching.

Why? Because all capacities of the edges going out of  $s$  (source) are equal to 1 and all capacities of the edges coming to  $t$  (sink) are equal to 1. Therefore, we have both inequalities together, which defines:  $size(f^*) = |M^*|$  maximum flow equals to maximum matching.

## Pennant Race Problem (1965)

The Pennant Race problem is:

**Input:** Given a baseball team  $A$ , a list of any other teams  $T_1, T_2, \dots, T_n$  to win the pennant against team  $A$ . There is a win/loss rate for all teams which already played the games.

**Question:** Is it possible that team  $A$  can end the season having won at least as many games as any other team?

**Conditions:**

- Since it's baseball, each game has winner and loser, no draw.
- All schedule games are played.

**Initial set up:**

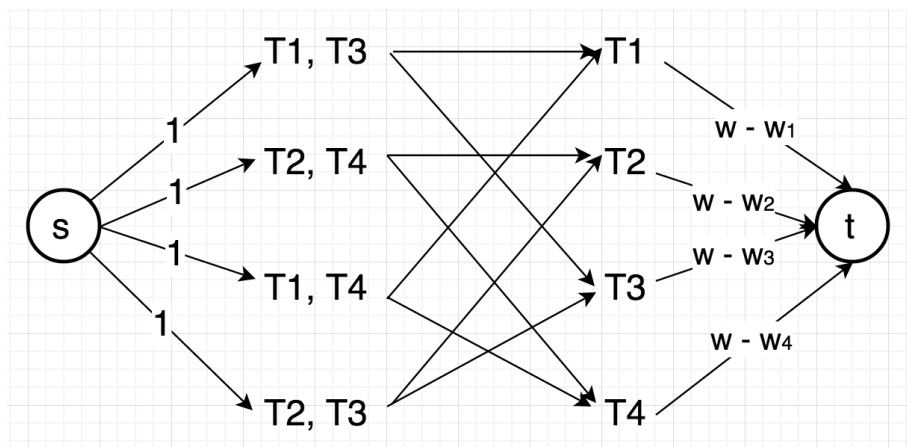

Consider a table where each team has # of wins over the played games, potential winning points from the future games, and the set of the remaining games. For  $A$  we can calculate the potential winning points easily, just assume  $A$  won all the remaining games.

Team	# of wins	Potential win points (w)	Remaining games
A	3	6	(A, T <sub>1</sub> ), (A, T <sub>3</sub> ), (A, T <sub>4</sub> ),
T <sub>1</sub>	4 = w <sub>1</sub>		(T <sub>1</sub> , T <sub>3</sub> ), (T <sub>2</sub> , T <sub>3</sub> ), (T <sub>2</sub> , T <sub>4</sub> ),
T <sub>2</sub>	6 = w <sub>1</sub>		(T <sub>1</sub> , T <sub>4</sub> )
T <sub>3</sub>	5 = w <sub>1</sub>		
T <sub>4</sub>	4 = w <sub>1</sub>		

Under assumption that  $A$  will win all the remaining games:

- Let  $w = \#$  wins after  $A$  wins all the remaining games;
- Let  $w_i = \#$  wins for  $T_i$  (current);
- If  $w < w_i$  for some  $i$ , then  $A$  has no hope. Otherwise, consider the set of games remaining to be played  $\{(T_i, T_j)\}$  where  $i \neq j$ .

We can transform the problem into a Bipartite graph. The idea is to think about wins as of 1 unit flows. Thus each game will have one “flow” = “win” to a team. Assume,  $w > w_i$  for all  $i$ , such that we still have a hope before we run an algorithm.

**Edges:**

- ( $s, T_i, T_j$ ) with capacity 1;
- ( $T_i, T_j, T_i$ ) any capacity  $\geq 1$ ;
- ( $T_i, t$ ) with capacity  $w - w_i$ , the maximum number of games  $T_i$  can win without getting more wins than team  $A$ .

After constructing the graph, we run any algorithm to find the max flow of the bipartite graph. If  $size(max\ flow)$  is less than the number of games remaining to be played (after assuming team  $A$  wins all its remaining games), then team  $A$  has no hope..
